MD vs. QC on GPUs

“Classical” Molecular Dynamics	Quantum Chemistry (MO, PW, DFT, Semi-Emp)
Simulates positions of atoms over time; chemical-biological or chemical-material behaviors	Calculates electronic properties; ground state, excited states, spectral properties, making/breaking bonds, physical properties
Forces calculated from simple empirical formulas (bond rearrangement generally forbidden)	Forces derived from electron wave function (bond rearrangement OK, e.g., bond energies)
Up to millions of atoms	Up to a few thousand atoms
Solvent included without difficulty	Generally in a vacuum but if needed, solvent treated classically (QM/MM) or using implicit methods
Single precision dominated	Double precision is important
Uses cuBLAS, cuFFT, CUDA	Uses cuBLAS, cuFFT, OpenACC
Geforce (Accademics), Tesla (Servers)	Tesla recommended
ECC off	ECC on

Accelerating Discoveries

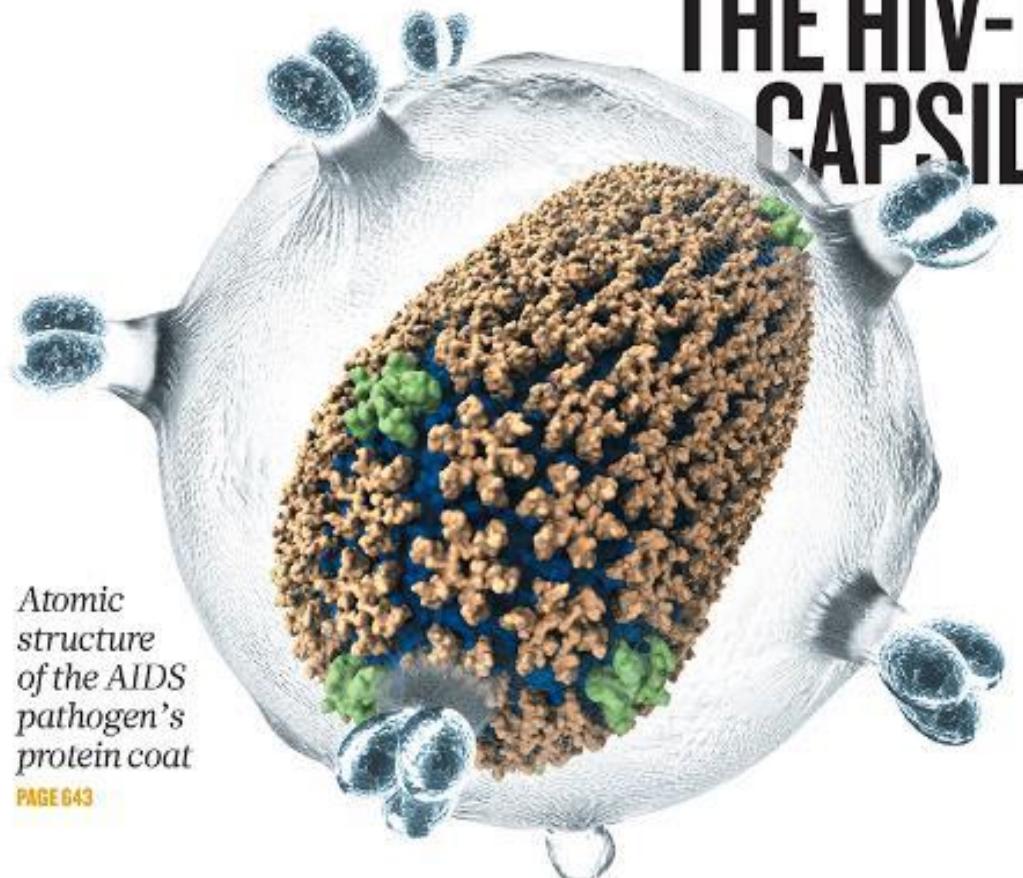

Using a supercomputer powered by the Tesla Platform with over 3,000 Tesla accelerators, University of Illinois scientists performed the first all-atom simulation of the HIV virus and discovered the chemical structure of its capsid – “the perfect target for fighting the infection.”

Without gpu, the supercomputer would need to be 5x larger for similar performance.

ABINIT on GPUS

- Speed in the parallel version:
 - For ground-state calculations, GPUs can be used. This is based on CUDA+MAGMA
 - For ground-state calculations, the wavelet part of ABINIT (which is BigDFT) is also very well parallelized : MPI band parallelism, combined with GPUs

GPAW

- Density Functional Theory (DFT) program package for electronic structure calculations
- Time-Dependent Density Functional Theory (TDDFT) is implemented in the linear response and time propagation schemes
- Can use real-space grids, atom centered basis functions or plane waves
- Random Phase Approximation (RPA) also available
- Scales to thousands of cores and suitable for large scale calculations
- Open Source software licensed under GPL

Ground state DFT calculation of 561 Au atom cluster on Blue Gene/P.

LibXC on GPUs

- A reusable library of >250 exchange-correlation functionals
- Used by 15 different codes (Abinit, GPAW, BigDFT, etc.)
- Can be a performance bottleneck for small systems
- Can “clone” existing functionals for GPU use with fairly minimal changes to existing LibXC code and parallelizes well over grid points
- More information:
 - <https://confluence.slac.stanford.edu/display/SUNCAT/libxc+on+GPUs>
- Work by Lin Li, Jun Yan, Christopher O’Grady (Stanford/SLAC)

	22	2.1	23%	10
	3.5	3.2	35%	1.1
	76	9.1		13/8.3

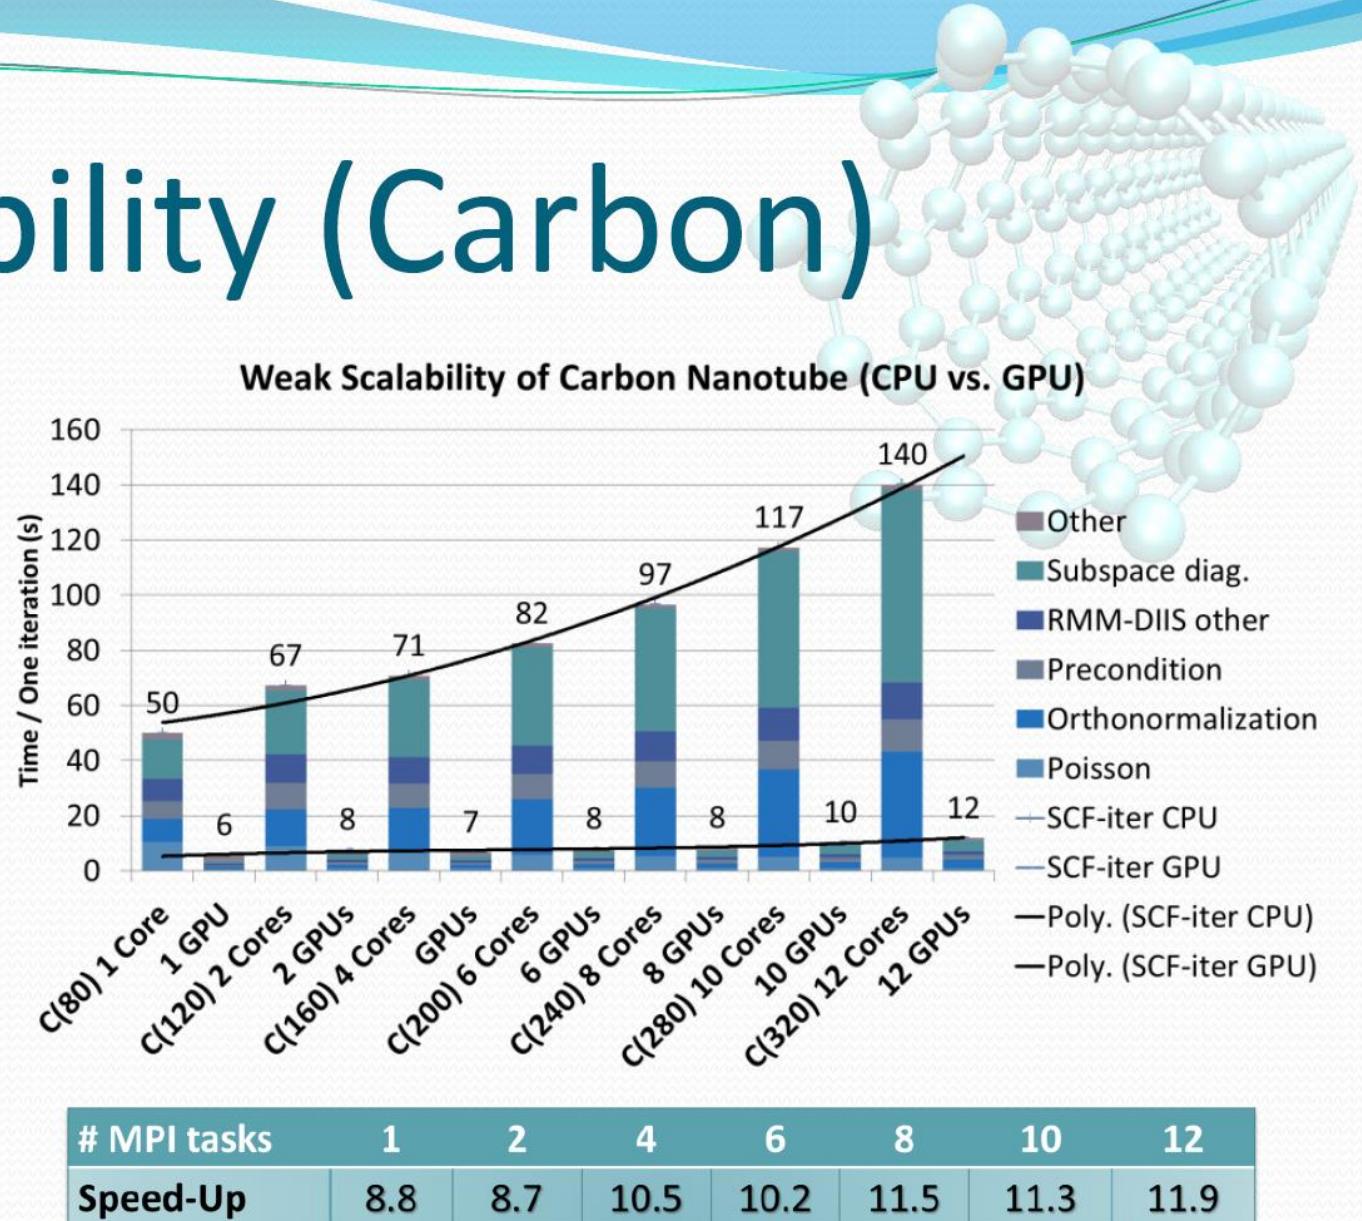

Multi-GPU Parallelization

- Parallelization is done with MPI
- Multiple GPUs can be used by domain decomposition or parallelization over k-points or spins
- Domain decomposition for the stencil operations involves exchanging boundary regions between neighboring nodes
- Communications between nodes require data movement: device memory → host memory → destinations node host memory → destinations node device memory.
- Overlaps receives, sends and computations in the middle part of the grid, BUT this causes issues with small grids
 - Small grids: Synchronous transfers
 - Medium grids: Asynchronous transfers
 - Large grids: Overlap calculations and asynchronous transfers
 - Combine of several wave functions and boundary regions into few large transfers

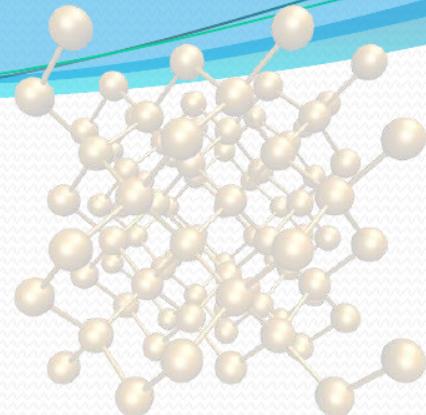

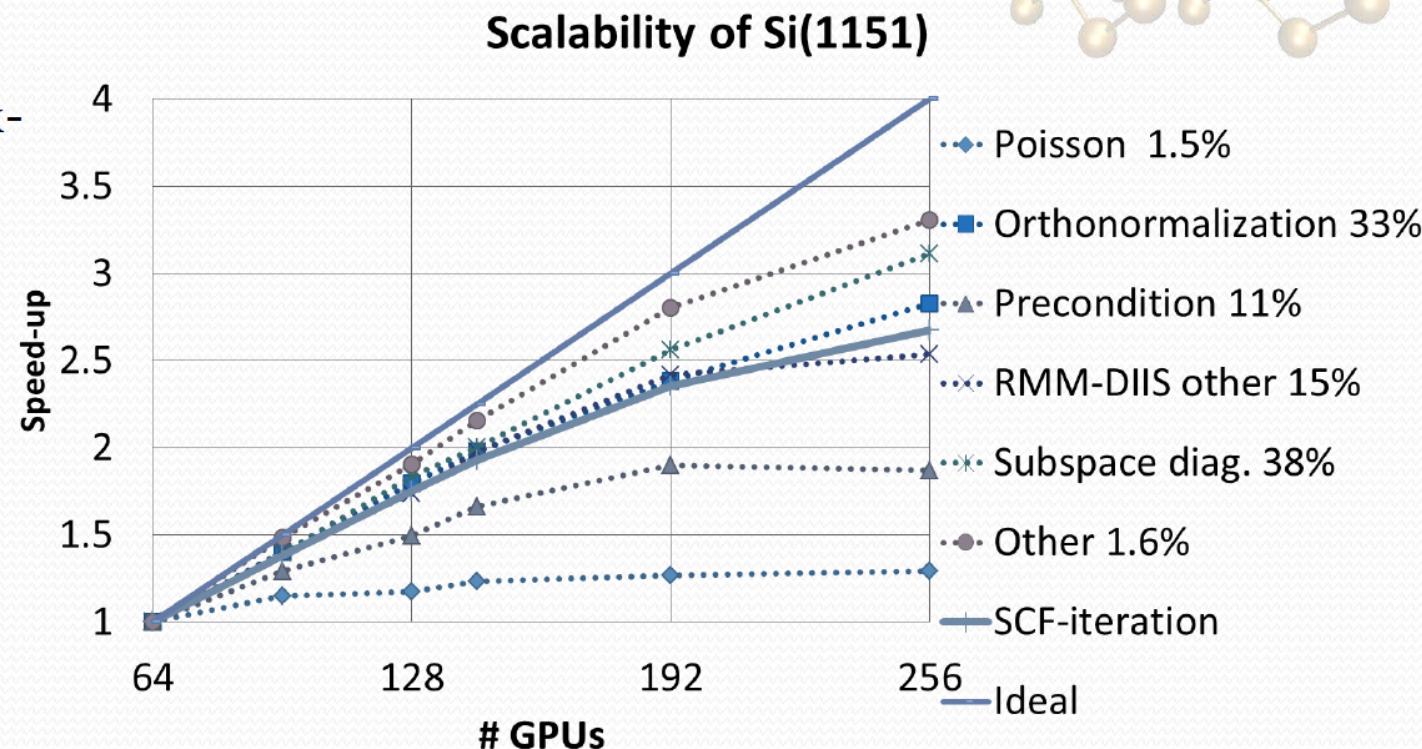

Weak Scalability (Carbon)

- The size of a carbon nanotube and the number of MPI tasks are varied from 80 atoms (240 states) to 320 atoms (1280 states) and 1 task to 12 tasks.
- Comparison between equal number of GPUs and CPU cores.
- CPU: Intel Xeon X5650 GPU: NVIDIA Tesla M2070
- Calculations performed on Vuori cluster at CSC

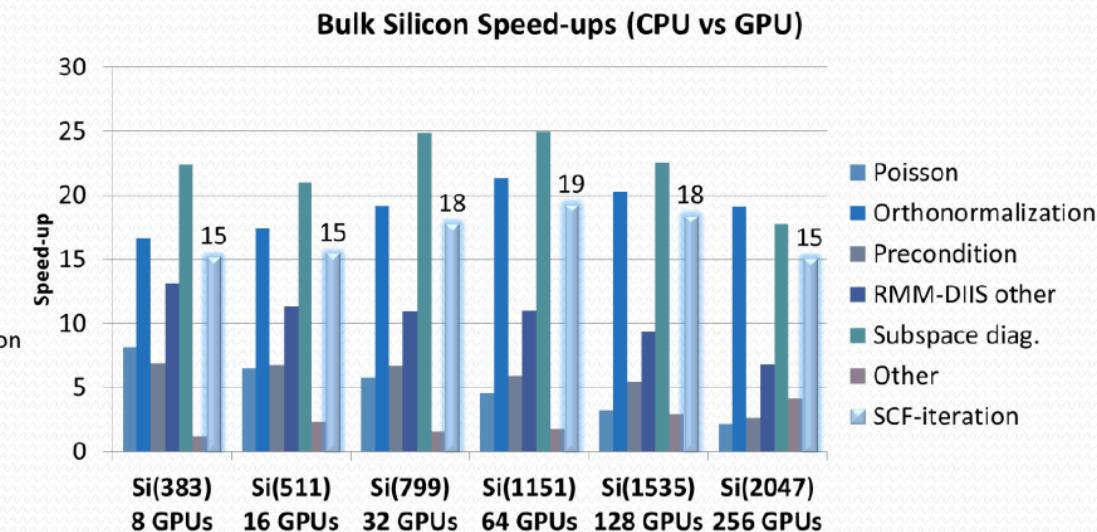

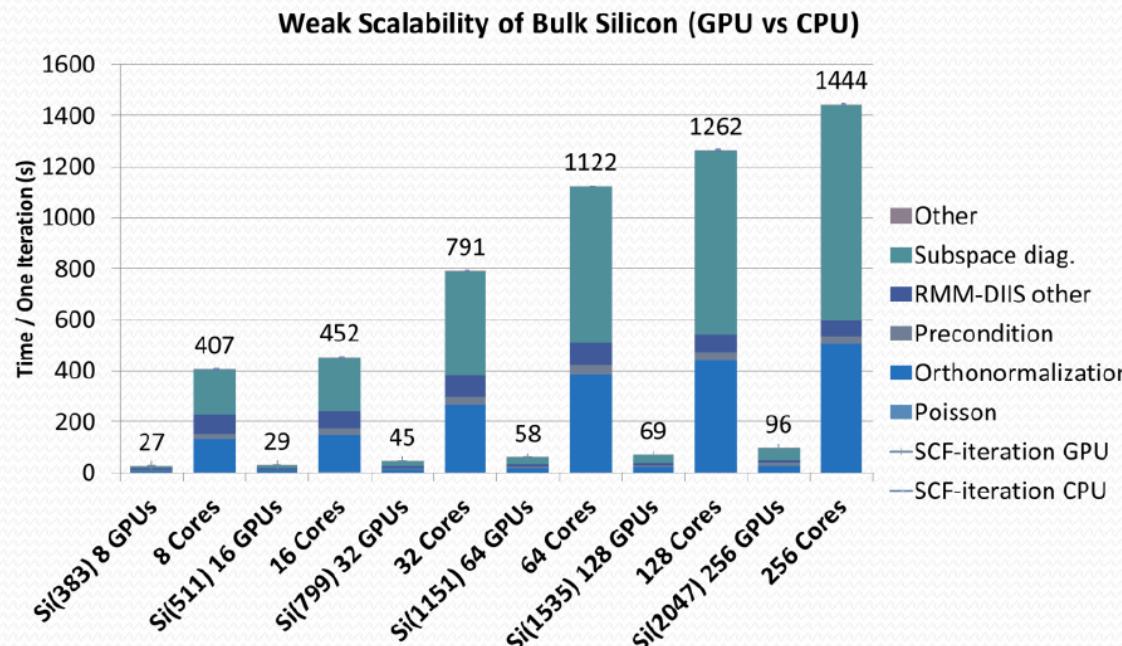

Strong Scalability

- Bulk silicon with 1151 atoms with periodic boundary conditions, 4604 bands and 1 k-point in the Brillouin zone.
- The number of GPUs is increased from 64 to 256.
- Grid size: 164x164x108
- Speed-up comparison to 64 GPUs.
- NVIDIA Tesla M2090
- Calculations performed on CURIE cluster in France at GENCI/CEA

Weak Scalability (Silicon)

- The size of bulk silicon system and the number of MPI tasks are varied from 383 atoms (1532 bands) to 2046 atoms (8188 bands) and 8 task to 256 tasks with periodic boundary conditions.
- The largest system requires about 1.3TB of memory for calculations.
- CPU: Intel Xeon E5640 GPU: NVIDIA Tesla M2090

Random Phase Approximation

GPAW Random Phase Approximation (RPA) code:

- 6000 lines of python, 1000 lines of C/CUDA (and re-uses many GPAW functions)
- Better than DFT for correlated materials, but more computationally expensive
- Useful for oxides, Van der Waals systems, etc.

GPU Techniques:

- Use BLAS₃ “zherk” instead of BLAS₂ “zher”
- Batch FFTs
- GPU kernels parallelized over atoms/bands/projector-functions
- No thunking: all calculations on GPU

Preliminary ((GPU+CPU)/CPU) speedup
for 202-electron N₂-on-Ru: 30x

Work by Jun Yan, Lin Li, Christopher O'Grady (Stanford/SLAC)
